2.3 3. Ranking Measures

https://networkx.github.io/documentation/networkx-1.10/reference/generated/networkx.algorithms.link_an PageRank computes a ranking of the nodes in the graph G based on the structure of the incoming links.

Mathematical PageRanks for a simple network, expressed as percentages. (Google uses a logarithmic scale.) Page C has a higher PageRank than Page E, even though there are fewer links to C; the one link to C comes from an important page and hence is of high value. If web surfers who start on a random page have an 85% likelihood of choosing a random link from the page they are currently visiting, and a 15% likelihood of jumping to a page chosen at random from the entire web, they will reach Page E 8.1% of the time. (The 15% likelihood of jumping to an arbitrary page corresponds to a damping factor of 85%.) Without damping, all web surfers would eventually end up on Pages A, B, or C, and all other pages would have PageRank zero. In the presence of damping, Page A effectively links to all pages in the web, even though it has no outgoing links of its own.

2.4 3.1 Page Ranking

https://en.wikipedia.org/wiki/PageRank

```
[279]: if not os.path.isfile('data/fea_sample/page_rank.p'):
    pr = nx.pagerank(train_graph, alpha=0.85)
    pickle.dump(pr,open('data/fea_sample/page_rank.p','wb'))
    else:
        pr = pickle.load(open('data/fea_sample/page_rank.p','rb'))
```

```
[280]: print('min',pr[min(pr, key=pr.get)])
    print('max',pr[max(pr, key=pr.get)])
    print('mean',float(sum(pr.values())) / len(pr))

min 1.6556497245737814e-07
    max 2.7098251341935827e-05
    mean 5.615699699389075e-07

[281]: #for imputing to nodes which are not there in Train data
    mean_pr = float(sum(pr.values())) / len(pr)
    print(mean_pr)
```

5.615699699389075e-07

3 4. Other Graph Features

3.1 4.1 Shortest path:

Getting Shortest path between two nodes, if nodes have direct path i.e directly connected then we are removing that edge and calculating path.

```
[282]: #if has direct edge then deleting that edge and calculating shortest path
      def compute_shortest_path_length(a,b):
          p = -1
          try:
              if train_graph.has_edge(a,b):
                  train_graph.remove_edge(a,b)
                  p= nx.shortest_path_length(train_graph,source=a,target=b)
                  train_graph.add_edge(a,b)
                  p= nx.shortest_path_length(train_graph,source=a,target=b)
              return p
          except:
              return -1

[287]: belongs_to_same_wcc(669354,1635354)
[287]: 0
```

3.3 4.3 Adamic/Adar Index:

Adamic/Adar measures is defined as inverted sum of degrees of common neighbours for given two vertices.

$$A(x,y) = \sum_{u \in N(x) \cap N(y)} \frac{1}{\log(|N(u)|)}$$

```
[288]: #adar index
      def calc_adar_in(a,b):
          sum=0
          try:
              n=list(set(train_graph.successors(a)).intersection(set(train_graph.

→successors(b))))
              if len(n)!=0:
                   for i in n:
                       sum=sum+(1/np.log10(len(list(train_graph.predecessors(i)))))
                  return sum
              else:
                  return 0
          except:
              return 0
[289]: calc_adar_in(1,189226)
[289]: 0
[290]: calc_adar_in(669354,1635354)
[290]: 0
```

3.4 4.4 Is persion was following back:

```
[291]: def follows_back(a,b):
    if train_graph.has_edge(b,a):
        return 1
    else:
        return 0

[292]: follows_back(1,189226)

[292]: 1
[293]: follows_back(669354,1635354)
[293]: 0
```

3.5 4.5 Katz Centrality:

https://en.wikipedia.org/wiki/Katz_centrality

https://www.geeksforgeeks.org/katz-centrality-centrality-measure/ Katz centrality computes the centrality for a node based on the centrality of its neighbors. It is a generalization of the eigenvector centrality. The Katz centrality for node i is

$$x_i = \alpha \sum_j A_{ij} x_j + \beta,$$

where A is the adjacency matrix of the graph G with eigenvalues

The parameter

β

controls the initial centrality and

$$\alpha < \frac{1}{\lambda_{max}}$$
.

0.0007483800935562018

3.6 4.6 Hits Score

The HITS algorithm computes two numbers for a node. Authorities estimates the node value based on the incoming links. Hubs estimates the node value based on outgoing links.

https://en.wikipedia.org/wiki/HITS_algorithm

```
[297]: if not os.path.isfile('data/fea_sample/hits.p'):
    hits = nx.hits(train_graph, max_iter=100, tol=1e-08, nstart=None,
    →normalized=True)
    pickle.dump(hits,open('data/fea_sample/hits.p','wb'))
else:
    hits = pickle.load(open('data/fea_sample/hits.p','rb'))

[298]: print('min',hits[0][min(hits[0], key=hits[0].get)])
    print('max',hits[0][max(hits[0], key=hits[0].get)])
    print('mean',float(sum(hits[0].values())) / len(hits[0]))
```

min 0.0 max 0.004868653378780953 mean 5.615699699344123e-07

4.4 5.4 Adding new set of features

we will create these each of these features for both train and test data points

```
Weight Features
weight of incoming edges
weight of outgoing edges
weight of incoming edges + weight of outgoing edges
weight of incoming edges * weight of outgoing edges
2*weight of incoming edges + weight of outgoing edges
weight of incoming edges + 2*weight of outgoing edges
Page Ranking of source
Page Ranking of dest
```

katz of source katz of dest hubs of source hubs of dest authorities_s of source authorities_s of dest

Weight Features In order to determine the similarity of nodes, an edge weight value was calculated between nodes. Edge weight decreases as the neighbor count goes up. Intuitively, consider one million people following a celebrity on a social network then chances are most of them never met each other or the celebrity. On the other hand, if a user has 30 contacts in his/her social network, the chances are higher that many of them know each other. credit - Graph-based Features for Supervised Link Prediction William Cukierski, Benjamin Hamner, Bo Yang

$$W = \frac{1}{\sqrt{1+|X|}}\tag{3}$$

it is directed graph so calculated Weighted in and Weighted out differently

```
[308]: #weight for source and destination of each link
Weight_in = {}
Weight_out = {}
for i in tqdm(train_graph.nodes()):
    s1=set(train_graph.predecessors(i))
    w_in = 1.0/(np.sqrt(1+len(s1)))
    Weight_in[i]=w_in

    s2=set(train_graph.successors(i))
    w_out = 1.0/(np.sqrt(1+len(s2)))
    Weight_out[i]=w_out

#for imputing with mean
mean_weight_in = np.mean(list(Weight_in.values()))
mean_weight_out = np.mean(list(Weight_out.values()))
